

Introduction to Reinforcement Learning

DAVIDE BACCIU – BACCIU@DI.UNIPI.IT

UNIVERSITÀ DI PISA

Introduction

Positioning Reinforcement Learning

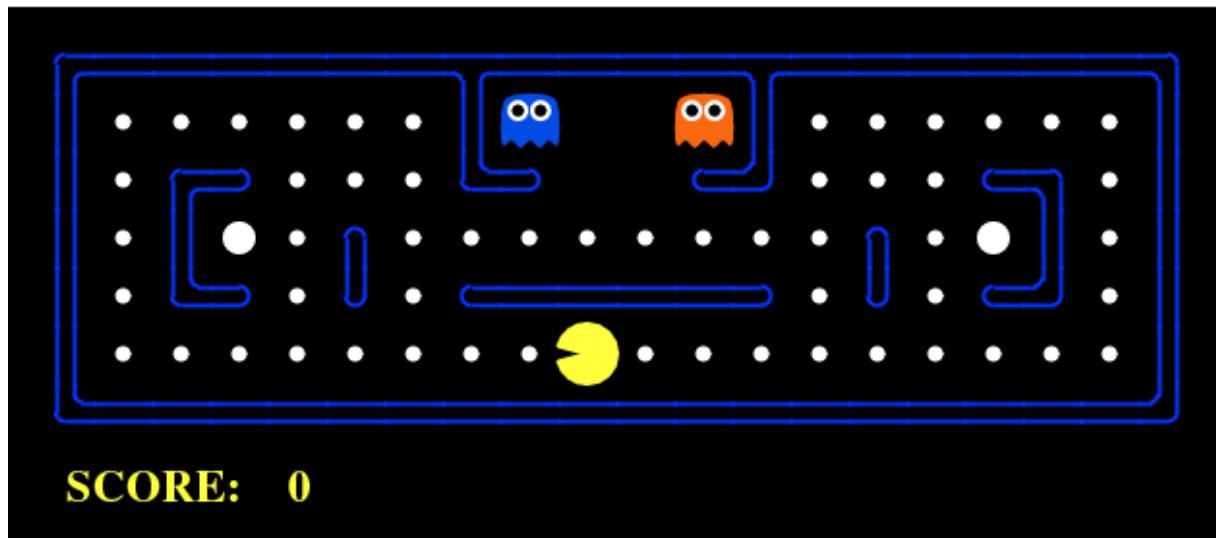

What characterizes Reinforcement Learning (vs other ML tasks)?

- ✓ No supervisor: only a *reward* signal
- ✓ Delayed asynchronous feedback
- ✓ Time matters (sequential data, continual learning)
- ✓ Agent's actions affect the subsequent data it receives (inherent non-stationarity)

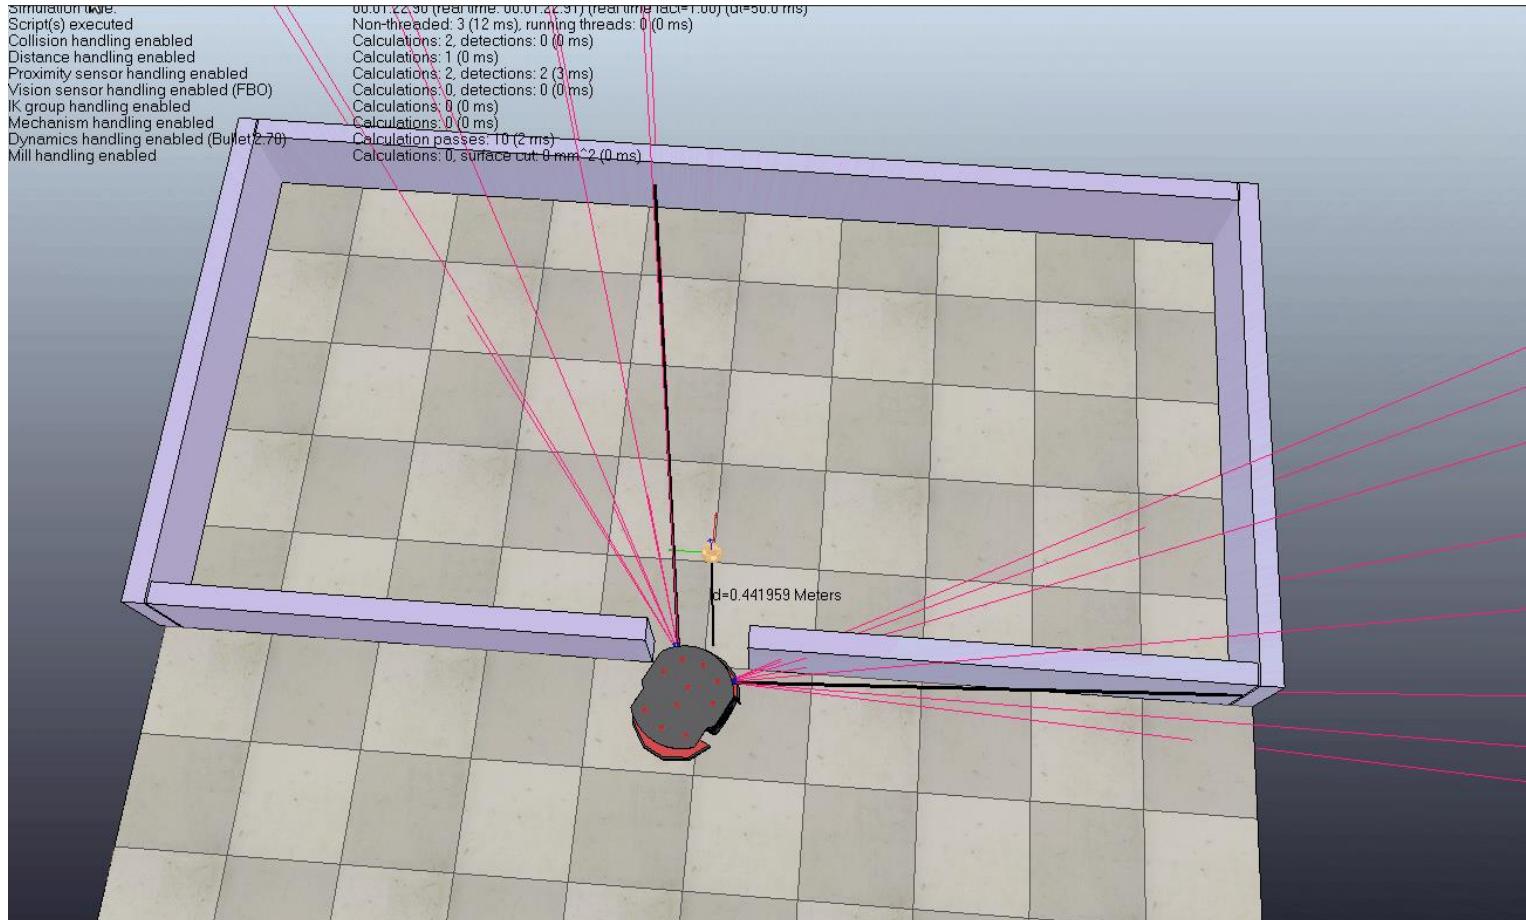

Using Reinforcement Learning

- ✓ Learning to maneuver vehicles
- ✓ Learn to control robots (walking, navigation, manipulation)
- ✓ Manage portfolios
- ✓ Play games
- ✓ Discover new molecules
- ✓ End-to-end learning with discrete structures

Game Playing

Navigation

Manipulation

Formalizing Reinforcement Learning

Rewards

- ✓ A reward R_t is a scalar feedback signal
- ✓ Indicates how well agent is doing at step t
- ✓ The agent's job is to maximise cumulative reward

Reinforcement learning is based on the [reward hypothesis](#)

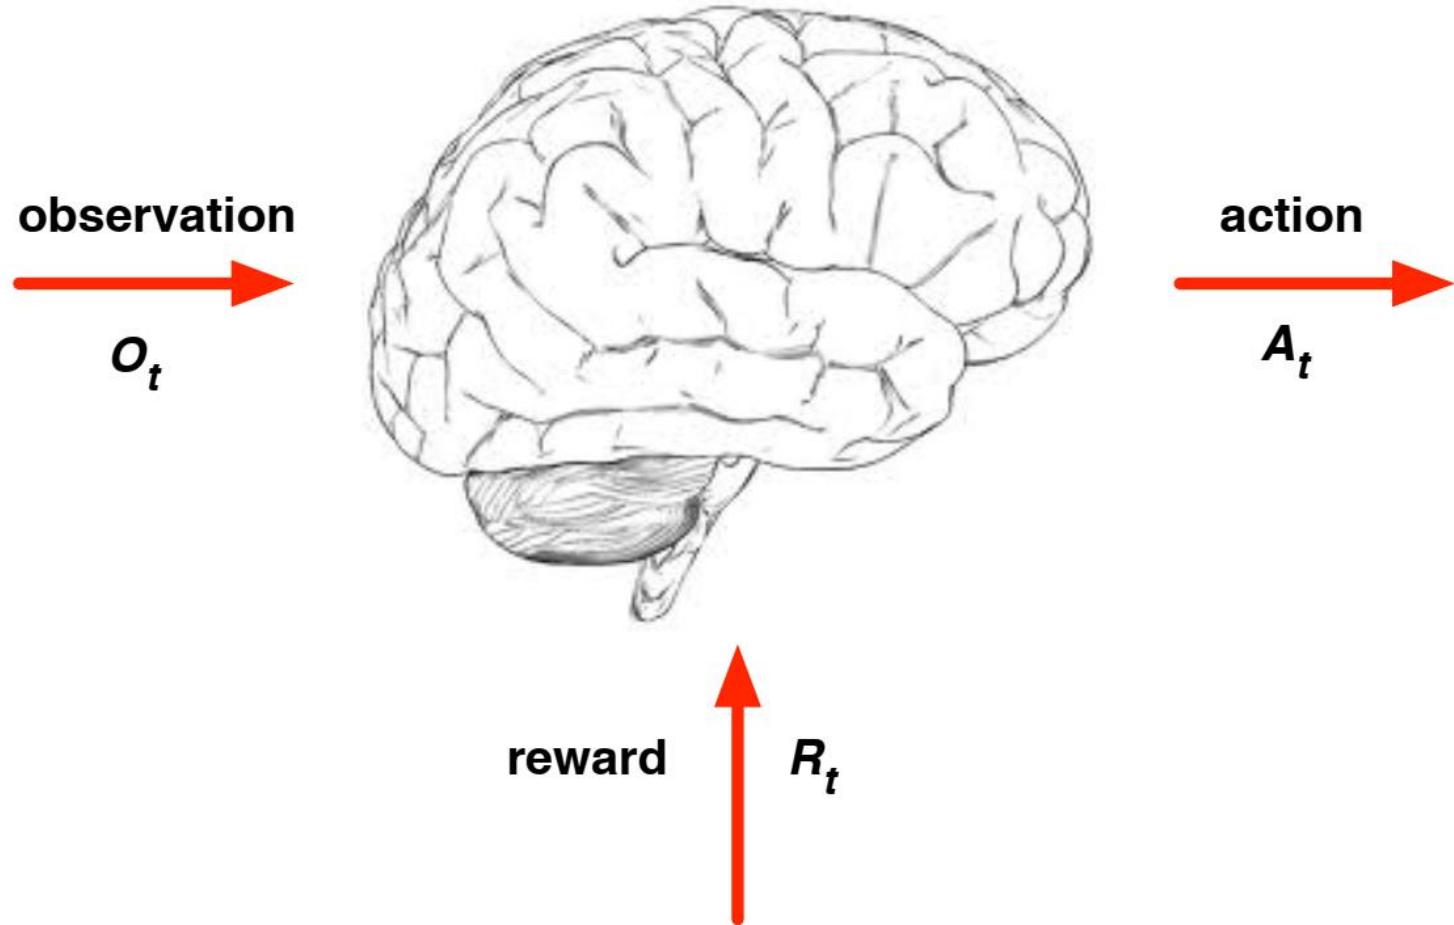

- ✓ All goals can be described by the maximisation of expected cumulative reward

What is a Reward?

- ✓ Learning to drive a car (+ve reward for getting places safely - -ve reward for crashing)
- ✓ Make a humanoid robot walk (+ve reward for forward motion, -ve reward for tripping over)
- ✓ Make a robot arm manipulate objects (+ve reward for goal achievement, -ve reward for object falling)
- ✓ Manage an investment portfolio (+ve reward for each \$ in bank)
- ✓ Play games (+=-ve reward for increasing/decreasing score)
- ✓ Discover new molecules (+ve reward for synthesizable molecule, -ve reward for toxic molecule)

Sequential Decision Making

- ✓ Goal: *select actions to maximise total future reward*
- ✓ Actions may have long term consequences
- ✓ Reward may be delayed
- ✓ It may be better to sacrifice immediate reward to gain more long-term reward
- ✓ Examples:
 - ✓ A financial investment (may take months to mature)
 - ✓ Refuelling a helicopter (might prevent a crash in several hours)
 - ✓ Blocking opponent moves (might help winning chances many moves from now)

Agent and Environment

- ✓ At each step t the agent:
 - ✓ Executes action A_t
 - ✓ Receives observation O_t
 - ✓ Receives scalar reward R_t
- ✓ The Environment:
 - ✓ Receives action A_t
 - ✓ Emits observation O_{t+1}
 - ✓ Emits scalar reward R_{t+1}
- ✓ t increments at environment step

History and State

The **history** is the sequence of observations, actions, rewards

$$H_t = O_1; R_1; A_1 \dots A_{t-1}; O_r; R_t$$

- ✓ i.e. all observable variables up to time t
- ✓ i.e. the sensorimotor stream of a robot or embodied agent

What happens next **depends on the history**:

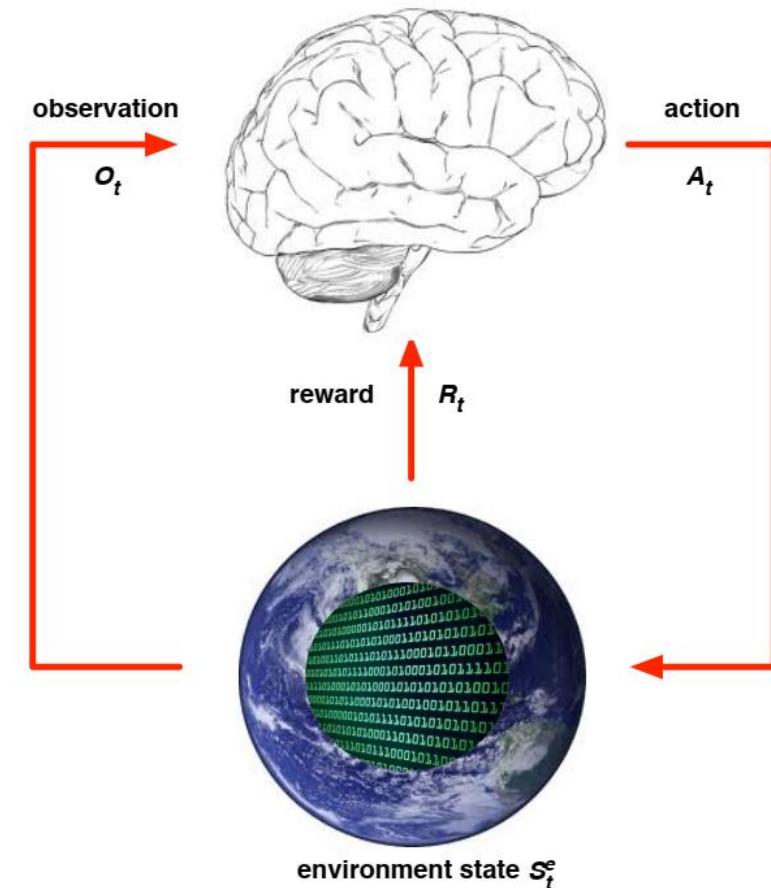

- ✓ The agent selects actions
- ✓ The environment selects observations/rewards

State S_t is the information used to determine what happens next and is a function of history

$$S_t = f(H_t)$$

Environment State

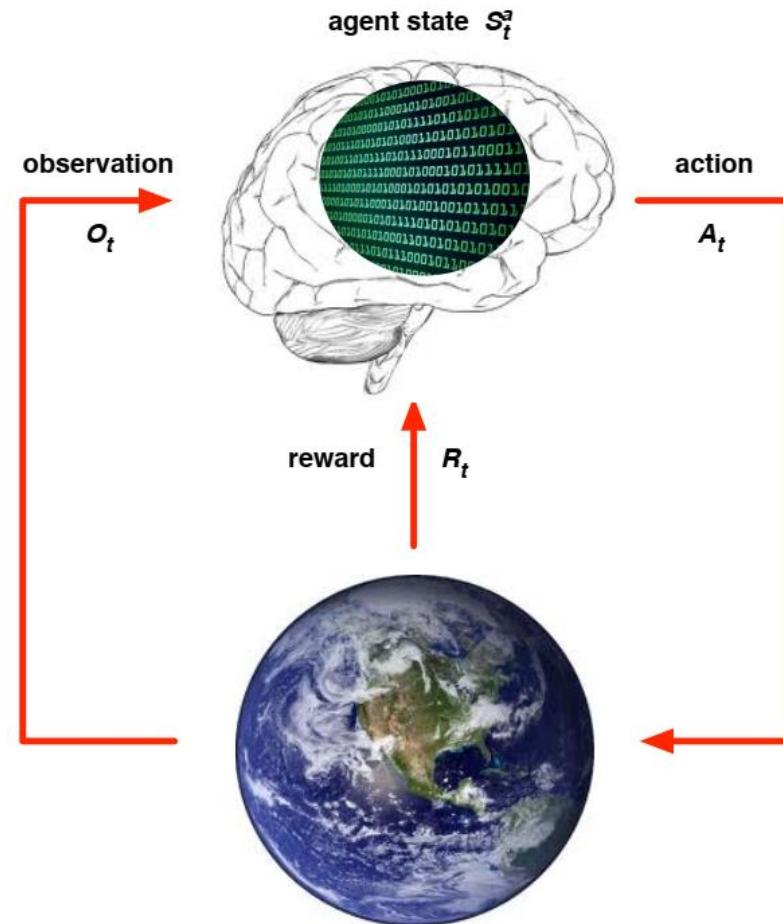

- ✓ The environment state S_t^e is the environment e private representation at time t
 - ✓ Whatever information the environment uses to generate the next observation/reward
- ✓ The environment state is not usually visible to the agent (unobservable environment)
- ✓ Even if S_t^e is visible, it may contain irrelevant information

Agent State

- ✓ The agent state S_t^a the internal representation owned by agent a
 - ✓ Whatever information the agent uses to select next action
- ✓ The agent state is the information used by reinforcement learning algorithms
- ✓ Generally speaking a function of history

$$S_t^a = f(H_t)$$

Information (Markov) State

An **information state (Markov state)** contains all useful information from the history

Definition (Markov State)

A state S_t is Markov if and only if

$$P(S_{t+1}|S_1, \dots, S_t) = P(S_{t+1}|S_t)$$

✓ The future is independent of the past given present (**d-separation**)

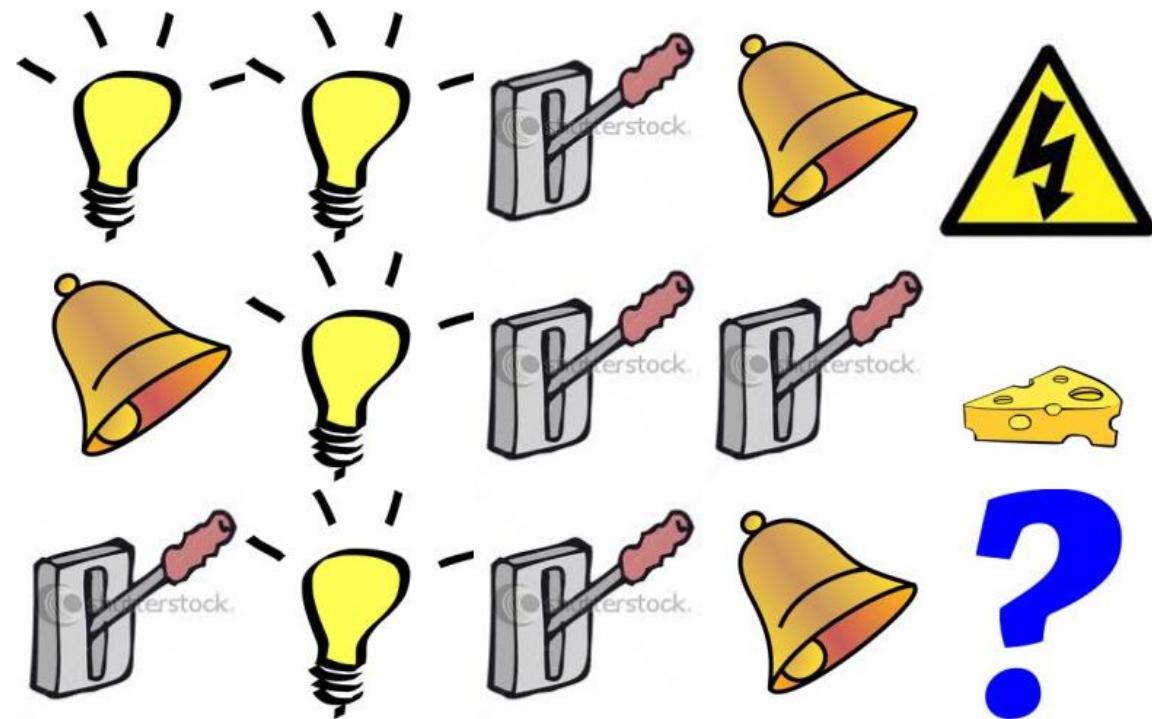

$$H_{1:t} \rightarrow S_t \rightarrow H_{t+1:\infty}$$

✓ The state is a **sufficient statistics** for the future

✓ The environment state S_t^e is Markov

✓ The history H_t is Markov

What's the best (agent) state model?

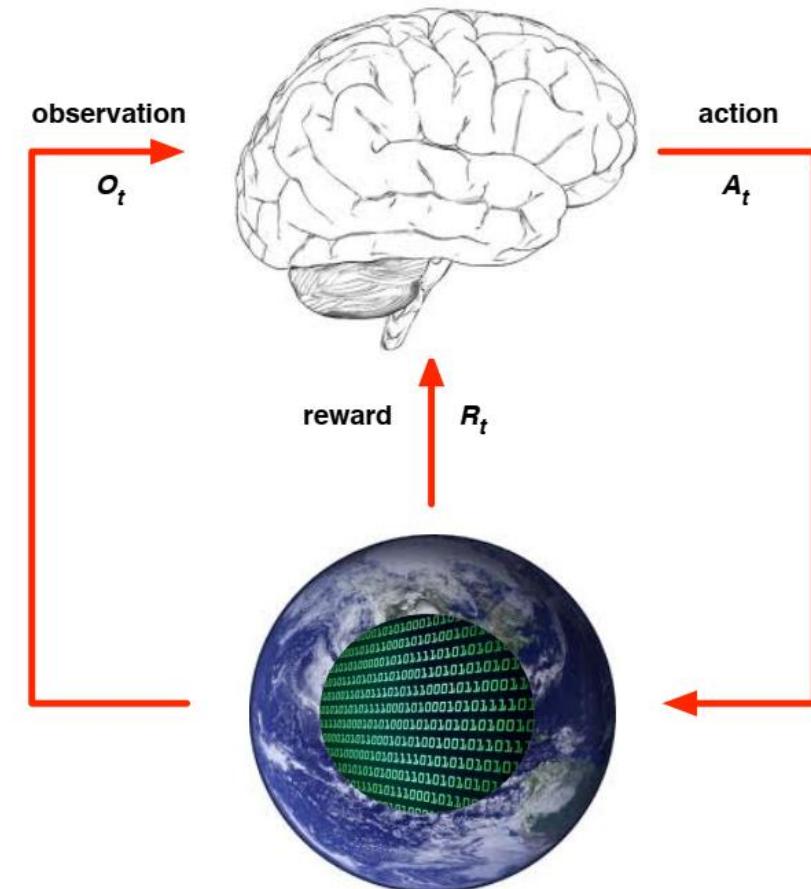

Fully Observable Environment

- ✓ Full observability \Rightarrow Agent directly observes the environment state

$$O_t = S_t^a = S_t^e$$

- ✓ Formally this is a **Markov Decision Process (MDP)**
- ✓ Next lecture (and much of the RL literature)

Partially Observable Environment

- ✓ Partial observability \Rightarrow Agent indirectly observes the environment
 - ✓ A robot with camera vision only may not know absolute location
 - ✓ A trading agent only observes current prices
 - ✓ A poker player only observes public cards
- ✓ Formally $S_t^a \neq S_t^e$ and the problem is a **Partially Observable Markov Decision Process (POMDP)**
- ✓ The agent needs to build its own state representation S_t^a
 - ✓ History: $S_t^a = H_t$
 - ✓ Beliefs on environment state: $S_t^a = [P(S_t^e = s^1) \dots P(S_t^e = s^N)]$
 - ✓ A dynamic memory (RNN): $S_t^a = \sigma(W_s S_{t-1}^a + W_o O^t)$

Components of a Reinforcement Learning Agent

Key Components of an RL Agent

- ✓ **Policy**: agent's behaviour function
- ✓ **Value function**: how good is each state and/or action
- ✓ **Model**: agent's representation of the environment

An RL agent may include one or more of the above

Policy

- ✓ A **policy** π is the agent's behaviour
- ✓ It is a map from state s to action a
- ✓ Deterministic policy: $a = \pi(s)$
- ✓ Stochastic policy: $\pi(a|s) = P(A_t = a | S_t = s)$

Value Function

How “good” is a specific state/action for an agent?

Value Function

- ✓ The **value function** v is a predictor of future reward
- ✓ Used to evaluate the **goodness/badness of states**
- ✓ And therefore to select between actions, e.g

$$v_\pi(s) = \mathbb{E}_\pi[R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots | S_t = s]$$

Expected (discounted) future reward following policy π from state s

Model

✓ A model predicts what the environment will do next

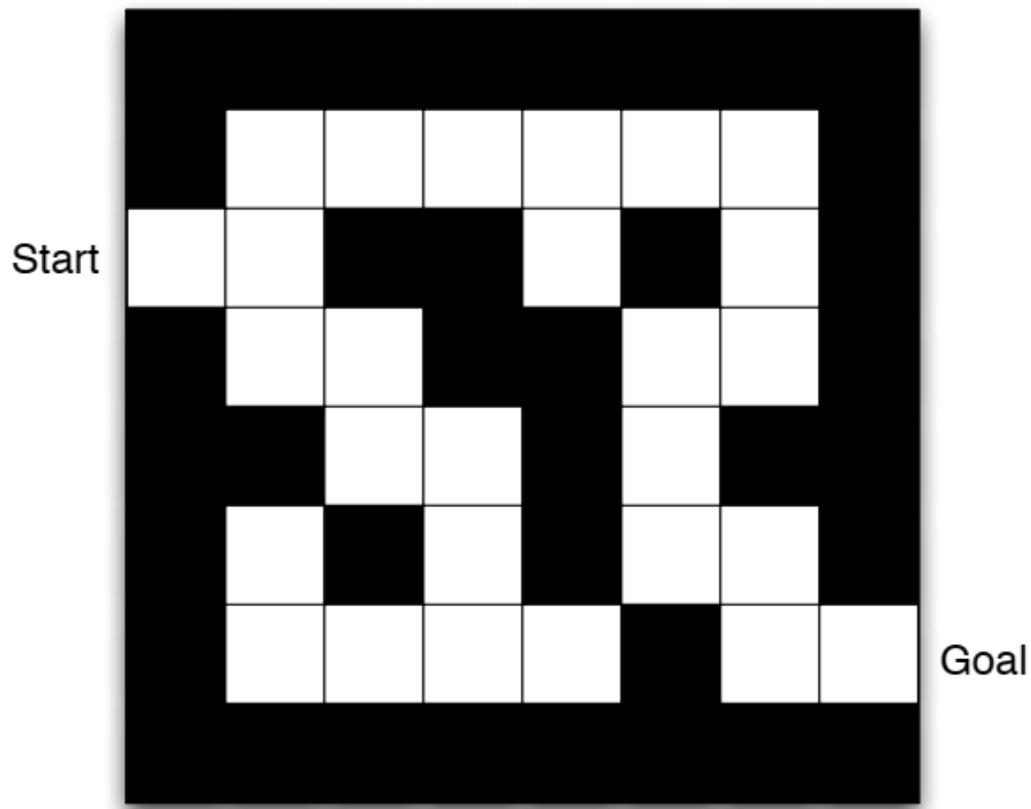

✓ Predict next state s' following an action a

$$\mathcal{P}_{ss'}^a = P(S_{t+1} = s' | S_t = s, A_t = a)$$

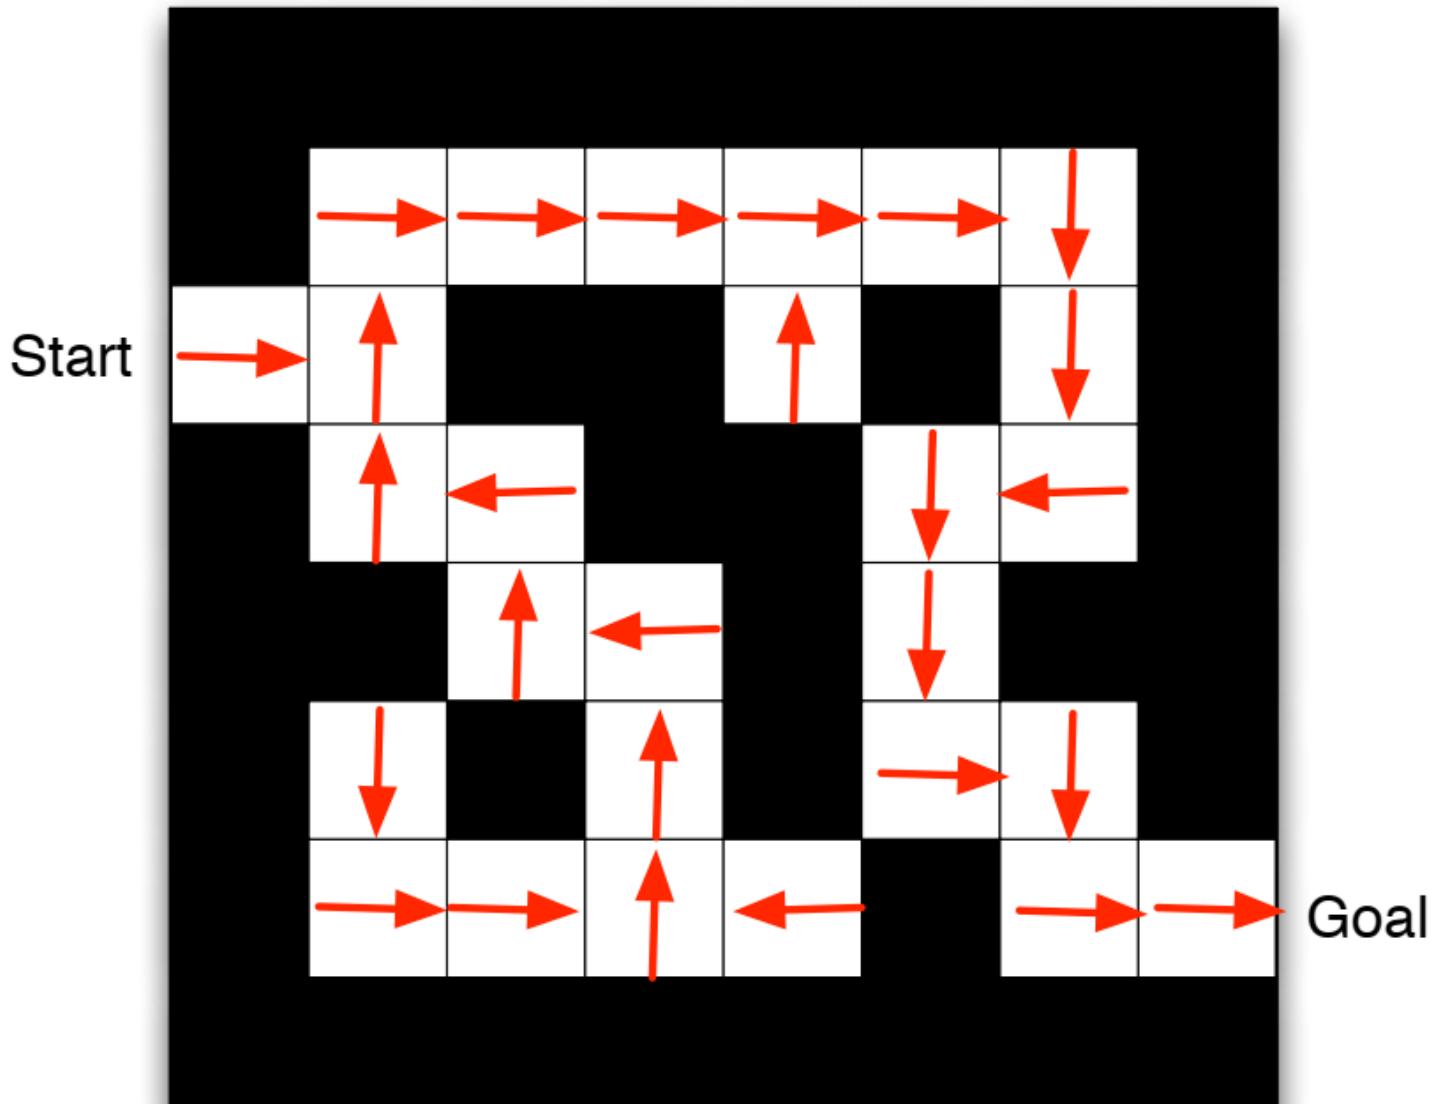

✓ Predict next reward

$$\mathcal{R}_s^a = \mathbb{E}[R_{t+1} | S_t = s, A_t = a]$$

A Forever Classic - The Maze Example

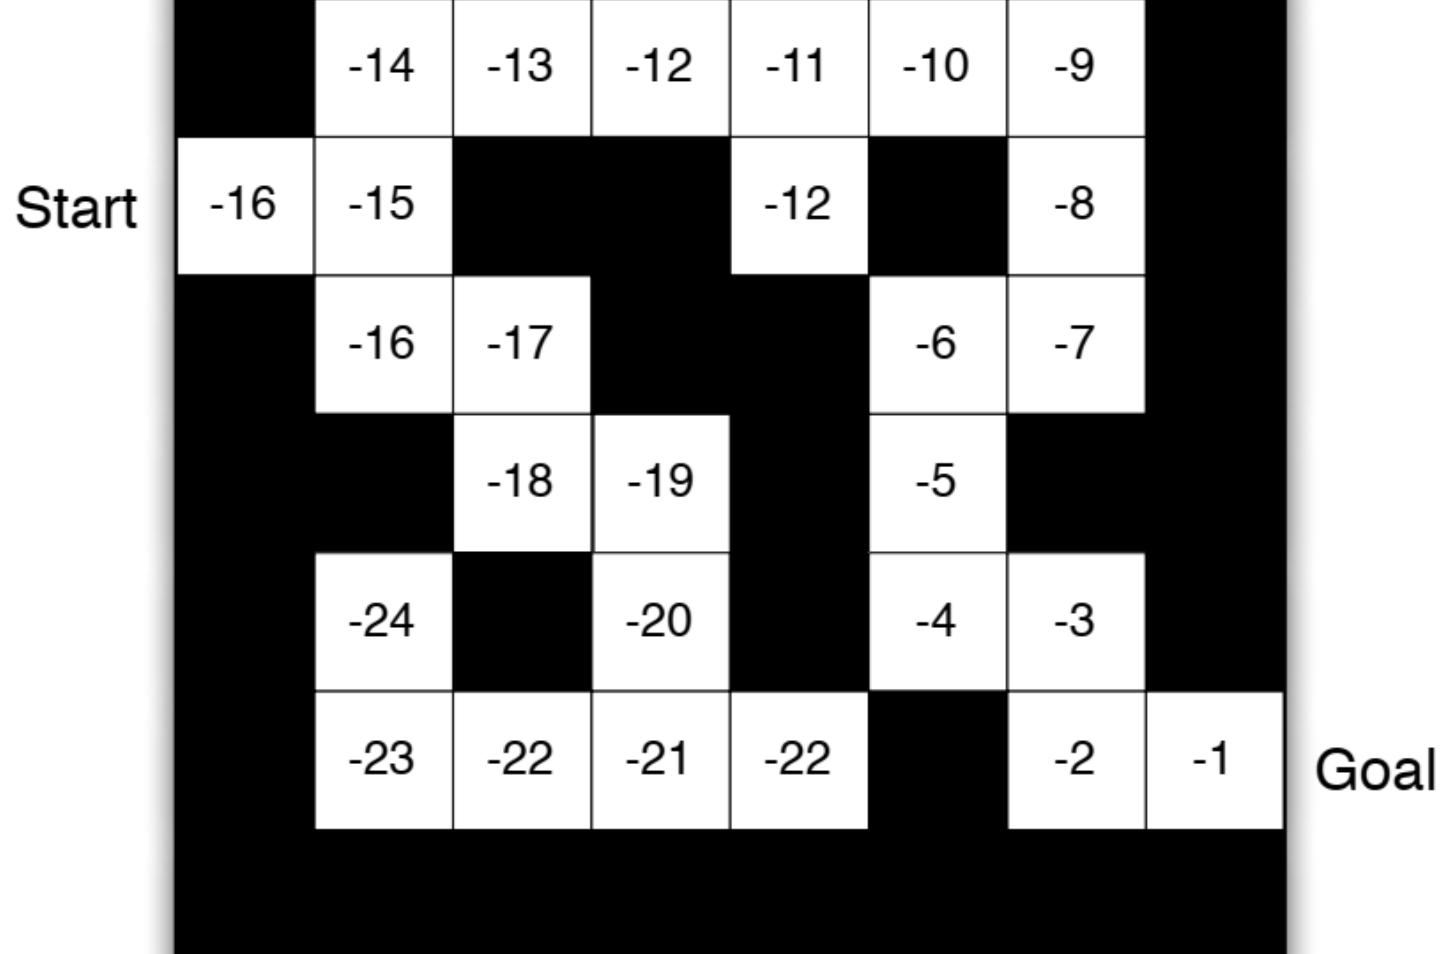

- ✓ Rewards: -1 per time-step
- ✓ Actions: N, E, S, W
- ✓ States: Agent location

Maze Example (Policy)

Arrows represent policy $\pi(s)$ for each state s

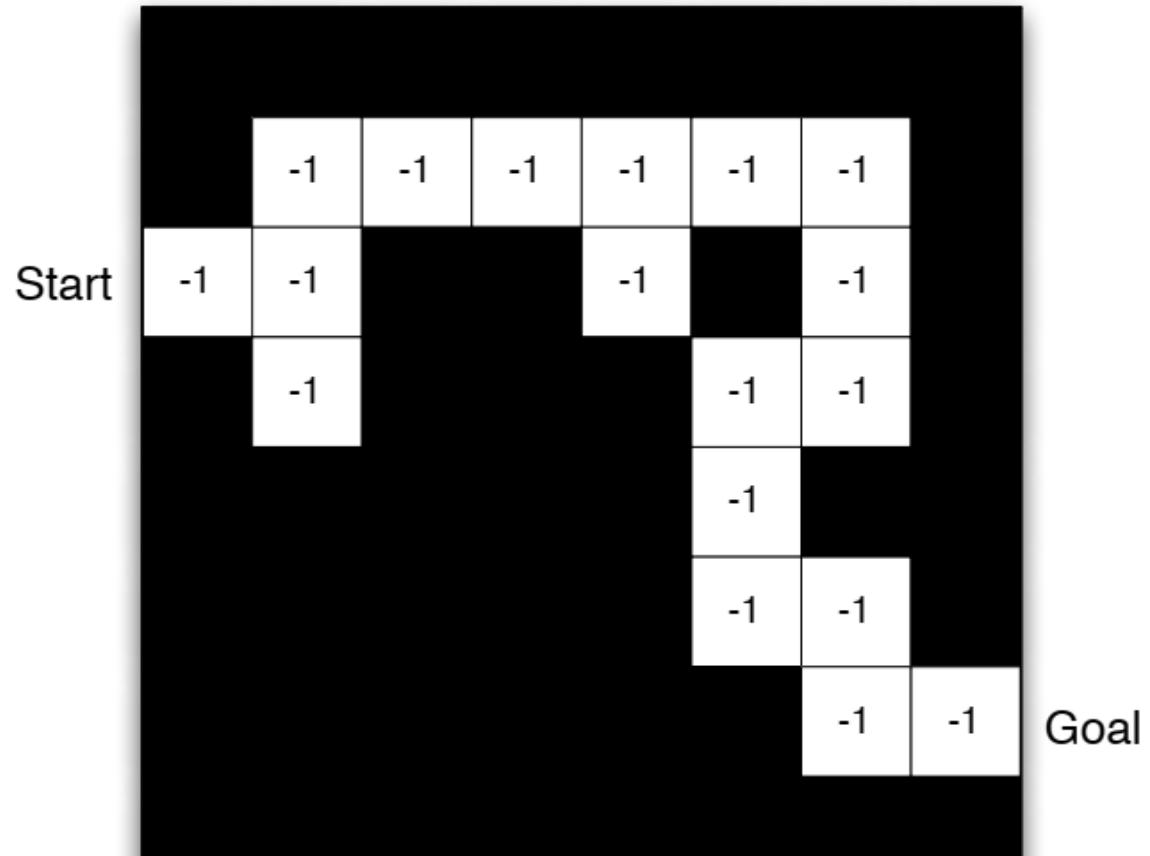

Maze Example (Value Function)

Numbers denote the value $v_\pi(s)$ for each s

Expected time to reach the goal

Maze Example (Model)

- ✓ Agent may have an internal (**imperfect**) model of the environment
 - ✓ How actions change the state
 - ✓ How much reward from each state
- ✓ **Grid Layout:** transition model $\mathcal{P}_{ss'}^a$
- ✓ **Numbers:** immediate reward model \mathcal{R}_s^a

Characterizing RL Agents (I)

✓ Value Based

✓ Policy (Implicit)

✓ Value Function

✓ Policy Based

✓ Policy

✓ Value Function

✓ Actor Critic

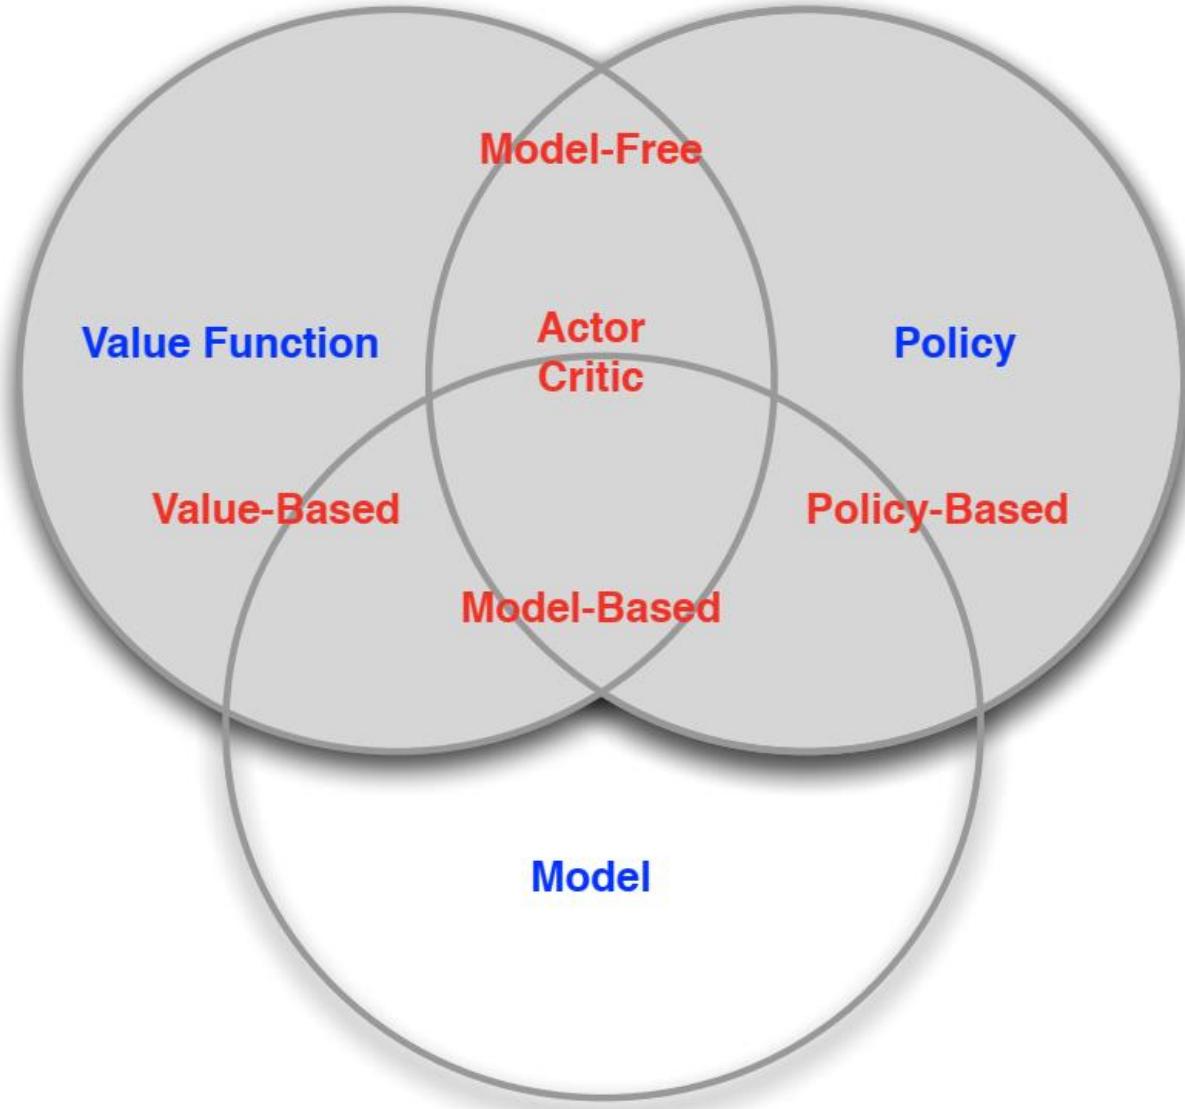

✓ Policy

✓ Value Function

Characterizing RL Agents (II)

- ✓ Model Free
- ✗ Model
- ✓ Policy and/or Value Function

- ✓ Model Based
- ✓ Model
- ✓ Policy and/or Value Function

A Taxonomy

Problems within Reinforcement Learning

Learning and Planning

Two fundamental problems in sequential decision making

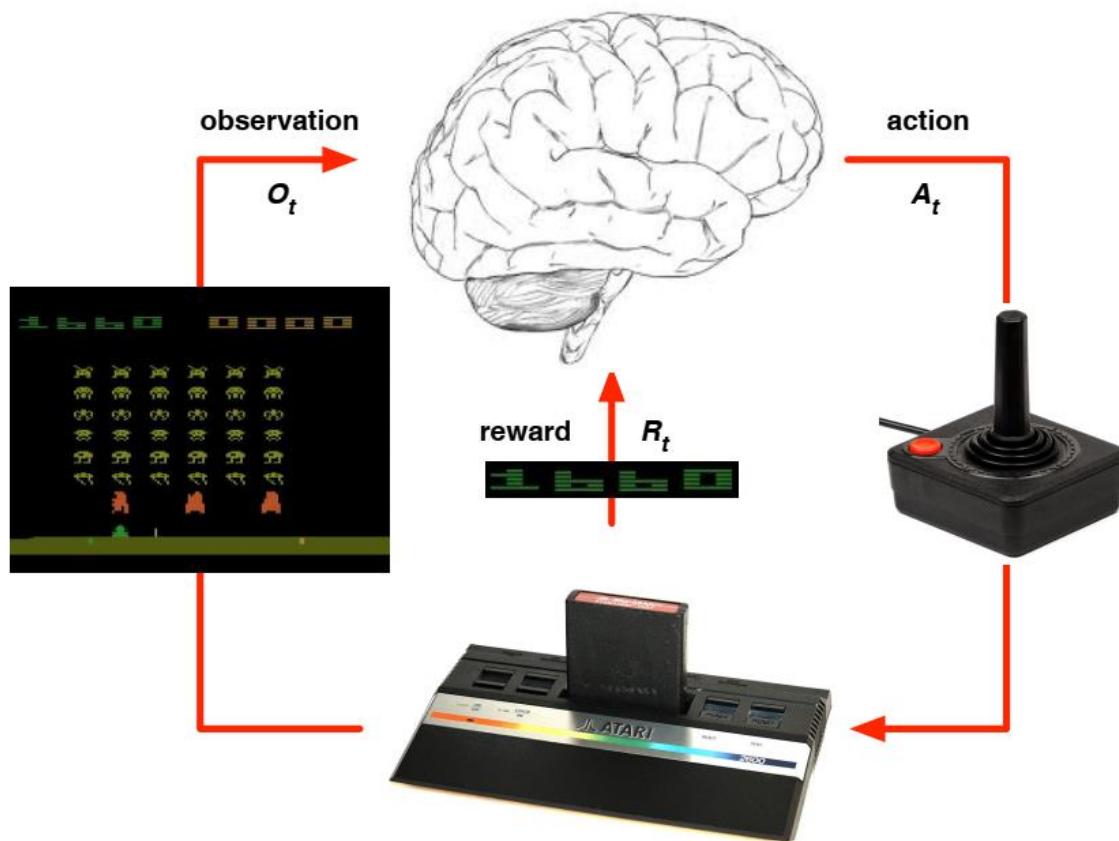

✓ Reinforcement Learning

- ✓ The environment is initially unknown
- ✓ The agent interacts with the environment
- ✓ The agent improves its policy

✓ Planning (reasoning, introspection, search,...)

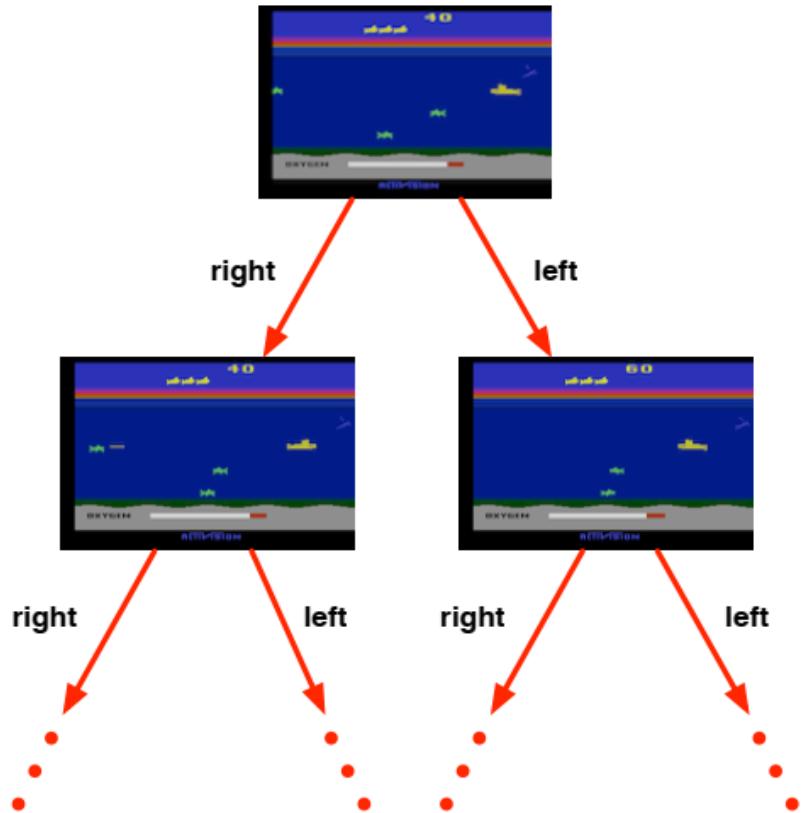

- ✓ A model of the environment is known
- ✓ The agent performs computations with its model (no external interaction)
- ✓ The agent improves its policy

Atari Example – Reinforcement learning

- ✓ Rules of the game are unknown
- ✓ Learn directly from interactive game-play
- ✓ Pick actions on joystick, see pixels and scores

Atari Example – Planning

- ✓ Rules of the game are known
- ✓ Agent contains emulator (model)
- ✓ If I take action a from state s :
 - ✓ what would the next state be?
 - ✓ what would the score be?
- ✓ Plan ahead to find optimal policy
 - ✓ e.g. tree search

Exploration Vs Exploitation

- ✓ Reinforcement Learning follows a trial-and-error process
 - ✓ The agent should discover a good policy
 - ✓ From its experiences of the environment
 - ✓ Without losing too much reward along the way
-
- ✓ Exploration finds more information about the environment
 - ✓ Exploitation exploits known information to maximise reward

Effective reinforcement learning requires to trade
between exploration and exploitation

Examples

- ✓ Restaurant Selection

- ✓ **Exploitation** - Go to your favourite restaurant

- ✓ **Exploration** - Try a new restaurant

- ✓ Holiday planning

- ✓ **Exploitation** – The camping site you go to since you are born

- ✓ **Exploration** – Hitchhike and follow the flow

- ✓ Game Playing

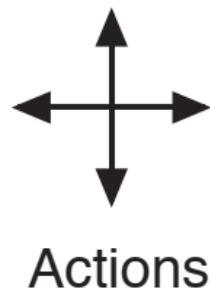

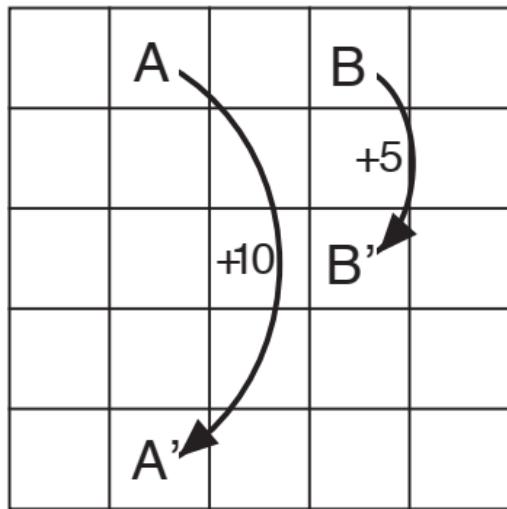

- ✓ **Exploitation** - Play the move you believe is best

- ✓ **Exploration** - Play an experimental move

Prediction & Control

- ✓ Prediction: evaluate the future
 - ✓ Given a policy
- ✓ Control: optimise the future
 - ✓ Find the best policy

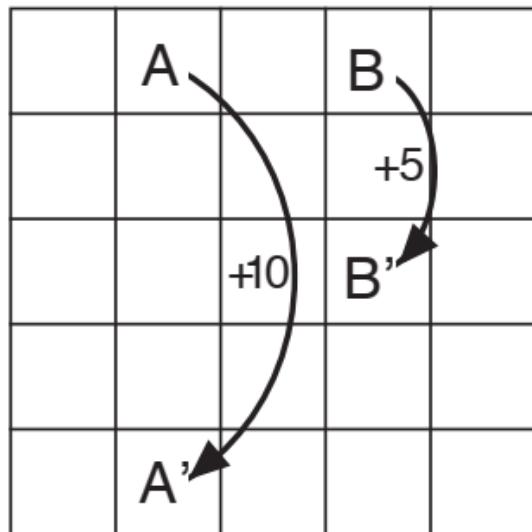

Gridworld Example - Prediction

3.3	8.8	4.4	5.3	1.5
1.5	3.0	2.3	1.9	0.5
0.1	0.7	0.7	0.4	-0.4
-1.0	-0.4	-0.4	-0.6	-1.2
-1.9	-1.3	-1.2	-1.4	-2.0

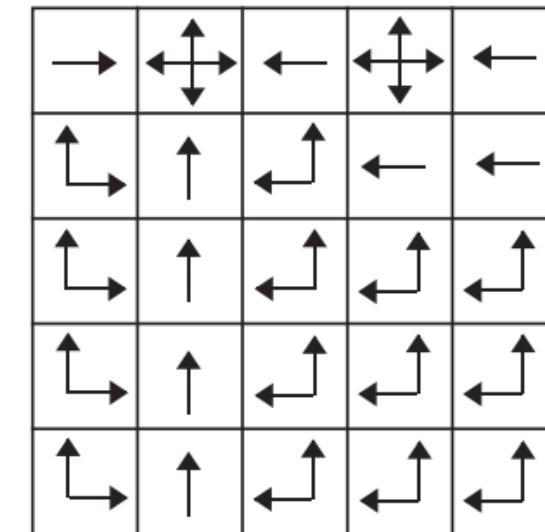

What is the value function for the uniform random policy?

Gridworld Example - Control

22.0	24.4	22.0	19.4	17.5
19.8	22.0	19.8	17.8	16.0
17.8	19.8	17.8	16.0	14.4
16.0	17.8	16.0	14.4	13.0
14.4	16.0	14.4	13.0	11.7

$$\mathcal{V}_*$$

$$\pi_*$$

What is the optimal value function over all possible policies?

What is the optimal policy?

Wrap-up

Take home messages

- ✓ Reinforcement learning is a general-purpose framework for decision-making
- ✓ Reinforcement learning is for an **agent with the capacity to act and observe**
- ✓ The **state is the sufficient statistics** to characterize the future
 - ✓ Depends on the history of actions and observations
 - ✓ Environment state Vs Agent state
- ✓ Success is measured by a scalar **reward signal**
 - ✓ The goal is to select actions to **maximise future reward** (exploit)
 - ✓ In order to be effective we should not forget to **explore**
